Parallel adaptive discontinuous Galerkin discretizations in space and time for linear elastic and acoustic waves

Willy Dörfler, Stefan Findeisen, Christian Wieners and Daniel Ziegler

Abstract. We introduce a space-time discretization for elastic and acoustic waves using a discontinuous Galerkin approximation in space and a Petrov–Galerkin scheme in time. For the dG method, the upwind flux is evaluated by explicitly solving a Riemann problem. Then we show well-posedness and convergence of the discrete system. Based on goal-oriented dual-weighted error estimation an adaptive strategy is introduced. The full space-time linear system is solved with a parallel multilevel preconditioner. Numerical experiments for acoustic and elastic waves underline the efficiency of the overall adaptive solution process.

Keywords. Space-time methods, discontinuous Galerkin finite elements, linear hyperbolic systems, elastic and acoustic wave equation, dual weighted residual error estimator.

AMS classification. 65N30.

1 Introduction

Modern discretizations of time-dependent PDEs consider the full problem in the space-time cylinder and aim to overcome limitations of classical approaches such as the method of lines (first discretize in space and then solve the resulting ODE) and the Rothe method (first discretize in time and then solve the PDE). A main advantage of a holistic space-time method is the direct access to space-time adaptivity and to the backward problem (required for the goal-oriented error control or the dual problem in optimization, see [13] for more details). Moreover, this allows for parallel solution strategies simultaneously in time and space.

Several space-time concepts were proposed (different conforming and non-conforming space-time finite elements [34, 10, 23, 21, 33, 31, 36, 24, 28], the parareal method [25, 18], wavefront relaxation [16] etc.) and this topic has become an rapidly growing field in numerical analysis and scientific computing.

A further motivation for developing space-time methods is the design of modern computer facilities with an enormous number of processor cores, where the parallel realization of conventional methods becomes inefficient. Since these machines allow a fully implicit space-time approach, new parallel solution techniques are required to solve the huge linear systems, particularly for time-dependent applications in three
spatial dimensions. Iterative solution techniques for full space-time discretizations were investigated, e.g., in [15, 29, 5, 35, 1, 2, 14, 38, 17, 37].

Here, we use in space a discontinuous Galerkin (DG) method for time-dependent first-order systems, see, e.g., [19], where this discretization is coupled with explicit time integration. This is applied to acoustic and elastic waves in [9] in combination with an adaptive space-time $hp$-strategy. We then extend these spatial DG discretization by a Petrov–Galerkin method in time with continuous ansatz space and discontinuous test space (cf. [3] for the implicit midpoint rule). The second-order formulation in space for elastic waves with implicit discontinuous Galerkin time discretization is considered in [22].

The DG approach uses the same variational space-time setting as discontinuous Petrov–Galerkin (DPG) methods for general linear first-order systems in space and time, see [6] for an overview and [11, 7] for space-time applications. For acoustic and elastic waves, the hybridization in space (applied to the second-order formulation) is presented in [30], and a hybrid space-time discontinuous Galerkin method is proposed in [39]. Both methods are implicit in every time slab, and only Dirichlet traces are used for the hybrid coupling. Space-time (Trefftz) discontinuous Galerkin methods for wave problems are analyzed in [10, 23].

Error estimation for linear wave equations require a backtracking of the error source as it is provided by a dual-primal error estimator. This achieves a reliable error control by solving the adjoint problem together with a goal-oriented technique [3].

Here we transfer our results for the linear transport equation and for the Maxwell system in [8] to acoustic and elastic waves. We start with an introduction of the first-order system for the wave equation and a suitable variational setting which provides stability of the space-time operator in a Hilbert space setting. Then we review the construction of discontinuous Galerkin methods for linear systems of conservation laws, and we compute the numerical flux for acoustic and elastic waves by solving the corresponding Riemann problem. In the next section we derive an explicit error representation (involving the solution of the dual problem), where we extend our approach in [8] by a different variant to estimate the interpolation error of the dual problem which can be estimated without additional regularity assumptions. We shortly summarize the construction of a suitable space-time multigrid preconditioner for the fully coupled implicit space-time discretization. Finally, the convergence of the method and the efficiency of the adaptive strategy is demonstrated for examples comparing the propagation of acoustic and elastic waves.
2 Linear elastic and acoustic waves

The prototype equation describing linear waves in homogeneous media is the second-order evolution equation for a scalar potential $\phi$

$$\partial_t^2 \phi = \Delta \phi$$

subject to initial and boundary conditions. Introducing the pressure $p = \partial_t \phi$ and the velocity $v = \nabla \phi$, we obtain the first-order system

$$\partial_t p = \nabla \cdot v,$$
$$\partial_t v = \nabla p$$

describing, e.g., acoustic waves. This system is now extended to describe linear elastic waves.

Waves in solids Let $\Omega \subseteq \mathbb{R}^D$ be a bounded Lipschitz domain, and let $[0, T]$ be a finite time interval. In dynamic models in continuum mechanics, the motion of a material point $x$ in the reference configuration $\Omega$ at time $t$ is described by the deformation vector $\varphi(t, x)$. The velocity is denoted by $v = \partial_t \varphi$. Elastic waves are determined by Newton’s law for the balance of momentum

$$\rho \partial_t v = \text{div} \sigma + b,$$

with the mass density $\rho$, acceleration $\partial_t v$, and the vector of body forces $b$, together with a constitutive relation for the stress $\sigma$ depending on the deformation gradient $F = D\varphi$. For elastic materials a response function $\hat{\Sigma}(\cdot)$ exists so that the stress is determined by the response $\sigma = \hat{\Sigma}(F)$. Then the stress rate is given by

$$\partial_t \sigma = D\hat{\Sigma}(D\varphi)(Dv).$$

Assuming small strains and $\varphi \approx \text{id}$, this is approximated by its linearization

$$\partial_t \sigma = C\varepsilon(v), \quad \varepsilon(v) = \text{sym}(Dv)$$

with the elasticity tensor $C = D\hat{\Sigma}(I)$. The balance of torsional moments yields that the stress is symmetric and that the stress rate only depends on the symmetric strain rate. In isotropic media the elasticity tensor $C\varepsilon = 2\mu\varepsilon + \lambda \text{trace}(\varepsilon)I$ is characterized by the Lamé parameters $\lambda \geq 0, \mu > 0$. Introducing the compression modulus $\kappa = \frac{2\mu + 3\lambda}{3}$ and the deviatoric stress $\text{dev}(\sigma) = \sigma - \frac{1}{3} \text{trace}(\sigma)I$ we obtain

$$C\varepsilon = 2\mu \text{dev}(\varepsilon) + \kappa \text{trace}(\varepsilon)I, \quad C^{-1} \sigma = \frac{1}{2\mu} \text{dev}(\sigma) + \frac{1}{3\kappa} \text{trace}(\sigma)I.$$
Elastic Waves
\[ \partial_t \sigma = C \varepsilon(v) \quad \text{in } (0, T) \times \Omega \]
\[ \rho \partial_t v = \text{div } \sigma + b \quad \text{in } (0, T) \times \Omega \]
\[ \sigma(0) = \sigma_0 \quad \text{at } t = 0 \text{ in } \Omega \]
\[ v(0) = v_0 \quad \text{at } t = 0 \text{ in } \Omega \]
\[ \sigma n = t_{\text{stat}} \quad \text{on } (0, T) \times \Gamma_{\text{stat}} \]
\[ v = g_{\text{kin}} \quad \text{on } (0, T) \times \Gamma_{\text{kin}} \]

Acoustic Waves
\[ \partial_t p = \kappa \text{div } v \quad \text{in } (0, T) \times \Omega \]
\[ \rho \partial_t v = \nabla p + b \quad \text{in } (0, T) \times \Omega \]
\[ p(0) = p_0 \quad \text{at } t = 0 \text{ in } \Omega \]
\[ v(0) = v_0 \quad \text{at } t = 0 \text{ in } \Omega \]
\[ p = p_{\text{stat}} \quad \text{on } (0, T) \times \Gamma_{\text{stat}} \]
\[ n \cdot v = g_{\text{kin}} \quad \text{on } (0, T) \times \Gamma_{\text{kin}} \]

Table 1. First-order differential systems for elastic waves in \((0, T) \times \Omega\) with initial conditions at \(t = 0\), and static and kinematic boundary conditions on \(\partial \Omega = \Gamma_{\text{stat}} \cup \Gamma_{\text{kin}}\).

**Acoustic waves in fluids** In fluids we assume that shear forces can be neglected, i.e., we consider the limit \(\mu \to 0\). Then, the stress \(\sigma = p I\) is isotropic with hydrostatic pressure \(p = \frac{1}{3} \text{trace } \sigma\), and compression waves are described by the system

\[ \partial_t p = \kappa \text{div } v, \quad \rho \partial_t v = \nabla p + b. \]

In particular this applies to acoustic waves in air or in a gas at fixed temperature. Note that this is only a formal derivation of the acoustic wave equation using the setting of continuum mechanics of solids, see Table 1 for comparing the elastic and acoustic setting. The linearization of conservation laws for compressible fluids with a pressure-dependent constitutive relation for the density results in the same system for acoustic waves.

**First-order differential systems** The previous examples are instances of a system of \(J\) equations in \(\mathbb{R}^D\)

\[ M \partial_t u + Au = f, \]

with a first order differential operator \(A\) and a weighting operator \(M\), see Table 2.

We introduce the Hilbert space \(H = L^2(\Omega; \mathbb{R}^J)\) with weighted inner product

\[ (v, w)_H = (Mv, w)_{0, \Omega}, \]

where we assume that the operator \(M \in L^\infty(\Omega, \mathbb{R}^{J_{\text{sym}} \times J})\) is uniformly positive. The analysis of the wave problems will be considered with homogeneous boundary conditions on \(\partial \Omega\) which are realized by the choice of a suitable domain \(D(A) \subset H\). We assume that the operator \(A\) is skew-adjoint in the domain, i.e.,

\[ (Av, w)_{0, \Omega} = -(v, Aw)_{0, \Omega}, \quad v, w \in D(A). \quad (2.1) \]

For the corresponding evolution operator \(L = M \partial_t + A\) on the space-time cylinder \(Q = (0, T) \times \Omega\) we also observe

\[ (Lv, w)_{0, Q} = -(v, Lw)_{0, Q}, \quad v, w \in C^1_c(Q; \mathbb{R}^J), \]
Elastic Waves | Acoustic Waves
---|---
\( u = (\sigma, v) \) | \( u = (p, v) \)
\( M(\sigma, v) = (C^{-1}\sigma, \rho v) \) | \( M(p, v) = (\kappa^{-1}p, \rho v) \)
\( A(\sigma, v) = -(\varepsilon(v), \text{div} \sigma) \) | \( A(p, v) = -(\text{div} v, \nabla p) \)
\( f = (0, b) \) | \( f = (0, b) \)
\( D(A) = H(\text{div}, \Omega; \mathbb{R}^{D \times D}) \times H^1_0(\Omega; \mathbb{R}^D) \) | \( D(A) = H^1(\Omega) \times H_0(\text{div}, \Omega) \)

Table 2. First-order differential systems \( M \partial_t u + Au = f \) and suitable domains \( D(A) \) for linear waves. Here, we choose kinematic boundary conditions (Dirichlet b.c. for elastic waves and Neumann b.c. for acoustic waves).

where \( C_1^c \) denotes the set of compactly supported differentiable mappings.

Depending on \( L \) we define the space

\[
H(L, Q) = \{ v \in L_2(Q; \mathbb{R}^J) : g \in L_2(Q; \mathbb{R}^J) \text{ exists with} \ (g, w)_{0,Q} = -(v, Lw)_{0,Q} \text{ for all } w \in C_1^c(Q; \mathbb{R}^J) \}.
\]

Then, \( L \) can be extended to this space, and \( H(L, \Omega) \) is a Hilbert space with respect to the weighted graph norm \( \|v\|_{L,Q} = \sqrt{(Mv, v)_{0,Q} + (M^{-1}Lv, Lv)_{0,Q}}. \)

Let \( V \subset H(L, Q) \) be the closure of \( \{ v \in C^1([0, T]; D(A)) : v(0) = 0 \} \) with respect to the graph norm. In particular, the space \( V \) includes homogeneous initial conditions. Then we define \( W = L(V) \subset L_2(Q; \mathbb{R}^J) \) with the weighted norm \( \|w\|_W^2 = (Mw, w)_{0,Q}. \) On \( V \), we use the weighted graph norm \( \|v\|_V^2 = \|v\|_W^2 + \|M^{-1}Lv\|_W^2. \)

Since \( A \) is skew-adjoint, we obtain the operator estimate in weighted norms [8, Lem. 1]

\[
\|v\|_W \leq 2T \|M^{-1}Lv\|_W, \quad v \in V. \tag{2.2}
\]

This implies that \( L \in \mathcal{L}(V, W) \) is injective and the range is closed. Moreover, for \( f \in W \) a unique solution \( u \in V \) of the evolution equation

\[
Lu = f \tag{2.3}
\]

exists [8, Lem. 2]. This extends to initial values \( u(0) = u_0 \neq 0 \) by replacing \( f(t) \) with \( f(t) - Au_0 \). Also inhomogeneous boundary conditions can be analyzed by modifying the right-hand side when the existence of a sufficiently smooth extension of the boundary data can be assumed.

**Remark 2.1.** Since \( L \) mixes the derivatives in space and time, more regularity is difficult to show in this Hilbert space framework. Therefore, one can check the assumptions of the Lumer–Phillips theorem [32, Thm. 12.22] for the operator \( A \) in \( D(A) \), so that semigroup theory with more regularity can be applied, see, e.g., [12]. The application to wave equations is discussed in [20, Sect. 2.2].
3 Discontinuous Galerkin methods for linear systems of conservation laws

All wave equations discussed so far can be more specifically considered as a system of linear conservation laws

\[ M \partial_t u(t) + \text{div} F(u(t)) = f(t) \quad \text{for } t \in [0, T], \quad u(0) = u_0, \] (3.1)

with a linear flux function \( F(v) = [B_1 v, \ldots, B_D v] \) defined by symmetric matrices \( B_d \in \mathbb{R}^{J \times J}_{\text{sym}} \) such that

\[ A v = \text{div} F(v) = \sum_{d=1}^{D} B_d \partial_d v. \]

Traveling waves In the case of constant coefficients in \( \Omega = \mathbb{R}^D \), special solutions can be constructed as follows. For a given unit vector \( n = (n_1, \ldots, n_D)^\top \in \mathbb{R}^D \), we have \( n \cdot F(u) = B_n u \) with the symmetric matrix \( B_n = \sum_{d=1}^{D} n_d B_d \). Then, for all eigenpairs \( (\lambda, w) \in \mathbb{R} \times \mathbb{R}^J \) of \( B_n w = \lambda M w \) and all sufficiently smooth functions \( a: \mathbb{R} \to \mathbb{R} \), the traveling wave propagating with velocity \( c = |\lambda| \)

\[ u(t, x) = a(n \cdot x - \lambda t) w \]

is a solution of (3.1) with initial value \( u_0(x) = a(n \cdot x) w \) and right-hand side \( f = 0 \).

This also applies to traveling waves with discontinuous amplitude: the piecewise constant function

\[ u(t, x) = \begin{cases} 
    a_L w & \text{in } Q_L = \{(t, x) \in [0, T] \times \mathbb{R}^D : n \cdot x - \lambda t < 0\}, \\
    a_R w & \text{in } Q_R = \{(t, x) \in [0, T] \times \mathbb{R}^D : n \cdot x - \lambda t > 0\}, 
\end{cases} \] (3.2)

with \( a_L, a_R \in \mathbb{R} \) is a weak solution, i.e., we have \( \int_{\mathbb{R}} \int_{\mathbb{R}^D} u \cdot L v \, dx \, dt = 0 \) for all \( v \in C^1_c(\mathbb{R} \times \mathbb{R}^D; \mathbb{R}^J) \).

The Riemann problem for linear conservation laws We now construct a weak solution of the Riemann problem, i.e., a piecewise constant weak solution with right-hand side \( f = 0 \) and the discontinuous initial function

\[ u_0(x) = \begin{cases} 
    u_L & \text{in } \Omega_L = \{x \in \mathbb{R}^D : n \cdot x < 0\}, \\
    u_R & \text{in } \Omega_R = \{x \in \mathbb{R}^D : n \cdot x > 0\}, 
\end{cases} \] (3.3)

with \( u_L, u_R \in \mathbb{R}^J \). Let \( \{(\lambda_j, w_j)\}_{j=1,\ldots,J} \) be the (necessarily \( M \)-orthogonal) set of eigenpairs, i.e.,

\[ B_n w_j = \lambda_j M w_j \quad \text{with} \quad w_k \cdot M w_j = 0 \quad \text{for } j \neq k. \] (3.4)
This defines a decomposition $B_n = B_n^- + B_n^+$ with

$$B_n^- v = \sum_{\lambda_j < 0} \lambda_j \frac{w_j \cdot M v}{w_j \cdot M w_j} M w_j, \quad B_n^+ v = \sum_{\lambda_j > 0} \lambda_j \frac{w_j \cdot M v}{w_j \cdot M w_j} M w_j.$$ 

By superposition of traveling waves, we obtain a weak solution of the Riemann problem

$$u(t, x) = \sum_{j=1}^{J} a_j (x \cdot n - \lambda_j t) w_j, \quad a_j(s) = \begin{cases} \frac{w_j \cdot M u_L}{w_j \cdot M w_j} s < 0, \\ \frac{w_j \cdot M u_R}{w_j \cdot M w_j} s > 0. \end{cases}$$

The solution of the Riemann problem at $(t, 0)$ for $t > 0$ defines the upwind flux on the interface $\partial \Omega_L \cap \partial \Omega_R$ by

$$n \cdot F_{\text{num}}(u_0) = \sum_{\lambda_j > 0} \frac{w_j \cdot M u_L}{w_j \cdot M w_j} B_n w_j + \sum_{\lambda_j < 0} \frac{w_j \cdot M u_R}{w_j \cdot M w_j} B_n w_j$$

$$= B_n u_L + B_n^- [u] \quad (3.5)$$

depending on the jump term $[u] = u_R - u_L$. By construction, the upwind flux is consistent, i.e., for $B_n u_L = B_n u_R$ we obtain $n \cdot F_{\text{num}}(u_0) = B_n u_L = B_n u_R$.

This transfers to the solution of the Riemann problem and the evaluation of the numerical flux in case of different material parameters in $\Omega_L$ and $\Omega_R$, i.e., two different matrices $M_L$ and $M_R$; see [20, Sect. 3.2] for details.

**Application to wave equations** For elastic waves with $\text{div} F(\sigma, v) = -(\varepsilon(v), \text{div} \sigma)$ we have the normal flux

$$n \cdot F(\sigma, v) = -\left( \frac{1}{2} (n \otimes v + v \otimes n) \right) \sigma n.$$ 

Now we consider the isotropic case, where $c_p = \sqrt{(2\mu + \lambda)/\rho}$ is the velocity of pressure waves, and $c_S = \sqrt{\mu/\rho}$ is the velocity of shear waves. The eigenvalues in (3.4) are $\pm c_p$, $\pm c_S$, and the corresponding eigenvectors are of the form $\left( 2\mu n \otimes n + \lambda I \right)$ and $\left( \mu (\tau \otimes n + n \otimes \tau) \right)$, where $\tau$ is a unit tangent vector, i.e., $\tau \cdot n = 0$. This yields

$$B_n^- [u] = -\frac{n \otimes n \sigma + \rho c_p n \cdot [v]}{2\rho c_p} \left( \frac{n \otimes n}{\rho c_p n} \sigma \right)$$

$$= -\frac{1}{2} \left( \frac{\tau \otimes n + n \otimes \tau}{\rho c_S} \right) [\sigma] + \rho c_S \tau \cdot [v] \left( \frac{1}{2} \left( \frac{\tau \otimes n + n \otimes \tau}{\rho c_S} \right) \right).$$
and inserting (3.5) results in the 2D upwind flux
\[
\mathbf{n} \cdot \mathbf{F}_{\text{num}}(\mathbf{u}_0) = -\left(\frac{1}{2}(\mathbf{n} \otimes \mathbf{v}_L + \mathbf{v}_L \otimes \mathbf{n}) - \frac{\mathbf{n} \cdot [\sigma]\mathbf{n} + \rho c_p [\mathbf{v}] \cdot \mathbf{n}}{2\rho c_p} \left(\frac{\mathbf{n} \otimes \mathbf{n}}{\rho c_p}\right)\right) - \frac{\mathbf{\tau} \cdot [\sigma]\mathbf{n} + \rho c_s [\mathbf{v}] \cdot \mathbf{\tau}}{2\rho c_s} \left(\frac{1}{2}(\mathbf{\tau} \otimes \mathbf{n} + \mathbf{n} \otimes \mathbf{\tau})\right).
\]

For acoustic waves with \(\text{div } \mathbf{F}(p, \mathbf{v}) = -(\text{div } \mathbf{v}, \nabla p)\) we obtain
\[
\mathbf{n} \cdot \mathbf{F}(p, \mathbf{v}) = -\left(\frac{\mathbf{n} \cdot \mathbf{v}}{p_l}\right),
\]
the velocity of sound \(c = \sqrt{\kappa/\rho}\), and the eigenvectors \(w_\pm = (\kappa \mp c \mathbf{n})\).

This yields \(B^- = -\frac{1}{2} \left(\frac{1}{\rho c} \frac{\mathbf{n}}{\mathbf{p}_l \mathbf{n} \otimes \mathbf{n}}\right)\) and thus the upwind flux
\[
\mathbf{n} \cdot \mathbf{F}_{\text{num}}(\mathbf{u}_0) = -\left(\frac{\mathbf{n} \cdot \mathbf{v}_L}{p_l \mathbf{n}}\right) - \frac{[p] + \rho c \mathbf{n} \cdot [\mathbf{v}]}{2\rho c} \left(\frac{1}{\rho c \mathbf{n}}\right).
\]

This extends to boundary conditions as follows.

For given values \((p_L, \mathbf{v}_L)\) the Riemann solution in \(\Omega_L\) takes the form
\[
\mathbf{u}(t, \mathbf{x}) = \begin{cases} 
(p_L, \mathbf{v}_L) & \mathbf{x} \cdot \mathbf{n} < tc, \\
(p_L, \mathbf{v}_L) + a \left(\frac{\kappa}{c} \mathbf{n}\right) & \mathbf{x} \cdot \mathbf{n} > tc,
\end{cases}
\]
and the parameter \(a\) is determined by boundary conditions. For \(p = p_{\text{stat}}\) on \(\partial \Omega_L\) we obtain \(a = \frac{p_{\text{stat}} - p_L}{\kappa}\), and for \(\mathbf{n} \cdot \mathbf{v} = g_{\text{kin}}\) on \(\partial \Omega_L\) we obtain \(a = \frac{g_{\text{kin}} - \mathbf{n} \cdot \mathbf{v}_L}{c}\).

This yields on the boundary
\[
\mathbf{n} \cdot \mathbf{F}_{\text{num}}(\mathbf{u}) = -\left(\frac{\mathbf{n} \cdot \mathbf{v}_L}{p_l \mathbf{n}}\right) - \frac{p_{\text{stat}} - p_L}{\kappa} \left(\frac{1}{\rho c \mathbf{n}}\right) = -\left(\frac{\mathbf{n} \cdot \mathbf{v}_L}{p_l \mathbf{n}}\right) - \frac{[p] + \rho c \mathbf{n} \cdot [\mathbf{v}]}{2\rho c} \left(\frac{1}{\rho c \mathbf{n}}\right) = \frac{p_{\text{stat}}}{\rho c} \left(\frac{1}{\rho c \mathbf{n}}\right)
\]
with \([p] = -2p_L\) and \(\mathbf{n} \cdot [\mathbf{v}] = 0\) for the static case (Dirichlet b.c.), and
\[
\mathbf{n} \cdot \mathbf{F}_{\text{num}}(\mathbf{u}) = -\left(\frac{\mathbf{v}_L \cdot \mathbf{n}}{p_l \mathbf{n}}\right) - \frac{g_{\text{kin}} - \mathbf{n} \cdot \mathbf{v}_L}{c} \left(\frac{1}{\rho c \mathbf{n}}\right) = -\left(\frac{\mathbf{v}_L \cdot \mathbf{n}}{p_l \mathbf{n}}\right) - \frac{[p] + \rho c \mathbf{n} \cdot [\mathbf{v}]}{2\rho c} \left(\frac{1}{\rho c \mathbf{n}}\right) + g_{\text{kin}} \left(\frac{1}{\rho c \mathbf{n}}\right)
\]
with \([p] = 0\) and \(\mathbf{n} \cdot [\mathbf{v}] = -2\mathbf{n} \cdot \mathbf{v}_L\) for the kinematic case (Neumann b.c.).
The discontinuous Galerkin discretization in space  We assume that $\Omega$ is a bounded polyhedral Lipschitz domain decomposed into a finite number of open elements $K \subset \Omega$ such that $\bar{\Omega} = \bigcup_{K \in \mathcal{K}} \bar{K}$, where $\mathcal{K}$ is the set of elements in space. Let $\mathcal{F}_K$ be the set of faces of $K \in \mathcal{K}$. For inner faces $f \in \mathcal{F}_K$ let $K_f$ be the neighboring cell such that $f = \partial K \cap \partial K_f$, and let $\mathbf{n}_K$ be the outer unit normal vector on $\partial K$. The outer unit normal vector field on $\partial \Omega$ is denoted by $\mathbf{n}$.

We select polynomial degrees $p_K$, and define the local spaces $H_{h,K} = \mathbb{P}_{p_K}(K; \mathbb{R}^J)$ and the global discontinuous Galerkin space
\[
H_h = \{ v_h \in L^2(\Omega)^J : v_h|_K \in H_{h,K} \text{ for all } K \in \mathcal{K} \}.
\]

For $v_h \in H_h$ we define $v_{h,K} = v_h|_K \in H_{h,K}$ for the restriction to $K$. In the semi-discrete problem
\[
M_h \partial_t u_h(t) + A_h u_h(t) = f_h(t), \quad t \in (0,T), \tag{3.6}
\]
the discrete mass operator $M_h \in \mathcal{L}(H_h, H_h)$ and the right-hand side $f_h \in H_h$ are the Galerkin approximations of $M$ and $f$ defined by
\[
(M_h v_h, w_h)_{0,\Omega} = (M v_h, w_h)_{0,\Omega} \quad v_h, w_h \in H_h, \tag{3.7}
\]
\[
(f_h, w_h)_{0,\Omega} = (f, w_h)_{0,\Omega} \quad w_h \in H_h.
\]

Note that $M_h$ is represented by a block diagonal positive definite matrix.

The discrete operator $A_h \in \mathcal{L}(H_h, H_h)$ is constructed as follows: Integration by parts yields for smooth ansatz functions $v$ and smooth test functions $\phi_K$
\[
(A v, \phi_K)_{0,K} = (\text{div} F(v), \phi_K)_{0,K}
\]
\[
= -(F(v), \nabla \phi_K)_{0,K} + \sum_{f \in \mathcal{F}_K} (\mathbf{n}_K \cdot F(v), \phi_K)_{0,f}.
\]

We then define for $v_h \in H_h$ and $\phi_{h,K} \in H_{h,K}$
\[
(A_h v_h, \phi_{h,K})_{0,K} = -(F(v_h,K), \nabla \phi_{h,K})_{0,K} + \sum_{f \in \mathcal{F}_K} (\mathbf{n}_K \cdot F_{h}^{\text{num}}(v_h), \phi_{h,K})_{0,f},
\]
where $\mathbf{n}_K \cdot F_{h}^{\text{num}}(v_h)$ is the upwind flux obtained from local solutions of Riemann problems. Again using integration by parts, we obtain
\[
(A_h v_h, \phi_{h,K})_{0,K} = (\text{div} F(v_h,K), \phi_{h,K})_{0,K}
\]
\[+ \sum_{f \in \mathcal{F}_K} (\mathbf{n}_K \cdot (F_{h}^{\text{num}}(v_h) - F(v_h,K)), \phi_{h,K})_{0,f}. \tag{3.8}
\]

On inner faces $f = \partial K \cap \partial K_f$ the difference $\mathbf{n}_K \cdot (F_{h}^{\text{num}}(v_h) - F(v_h,K))$ only depends on the jump term $[v_h]_{K,f} = v_{h,K_f} - v_{h,K}$, so that $\mathbf{n}_K \cdot (F_{h}^{\text{num}}(v) - F(v)) = 0$ on
all faces \( f \in \mathcal{F}_K \) for \( \mathbf{v} \in \mathcal{D}(A) \). On boundary faces, we define the jump term \([\mathbf{v}_h]_{K,f}\) depending on the boundary conditions as in the last paragraph. On \( H_h \) we define the operator \( A_h \) by

\[
(A_h \mathbf{v}_h, \phi_h)_{0,K} = \sum_{K \in \mathcal{K}} (A_h \mathbf{v}_h, \phi_h,_{K})_{0,K}, \quad \mathbf{v}_h, \phi_h \in H_h.
\]

By construction, the operator \( A_h \) satisfies the consistency condition

\[
(A \mathbf{v}, \phi_h)_{0,\Omega} = (A_h \mathbf{v}, \phi_h)_{0,\Omega}, \quad \mathbf{v} \in \mathcal{D}(A), \phi_h \in H_h,
\]

since the numerical flux \( F_{\text{num}} \) satisfies

\[
\sum_{K \in \mathcal{K}} (n_K \cdot F_{\text{num}}(\mathbf{v}_h, K), \mathbf{v})_{0,\partial K} = 0, \quad \mathbf{v} \in \mathcal{D}(A) \cap H^1(\Omega; \mathbb{R}^J)
\]

for \( \mathbf{v}_h \in H_h \). For our applications we can show that the upwind flux together with the described choice of the boundary flux guarantees that the discrete operator is non-negative and controls the nonconformity, i.e., a constant \( C_A > 0 \) exists such that

\[
(A_h \mathbf{v}_h, \mathbf{v}_h)_{0,\Omega} \geq C_A \sum_{f \in \mathcal{F}_K} \|n_K \cdot (F_{\text{num}}(\mathbf{v}_h) - F(\mathbf{v}_h, K))\|_{0,f}^2 \geq 0
\]

for all \( \mathbf{v}_h \in H_h \).

For elastic waves we obtain for \((\sigma_h, \mathbf{v}_h) \in H_h \) and \((\varphi_{K,h}, \psi_{K,h}) \in H_{K,h}\)

\[
(A_h(\sigma_h, \mathbf{v}_h), (\varphi_{K,h}, \psi_{K,h}))_{0,K} = -\left(\mathbb{E}(\mathbf{v}_K, h), \varphi_{K,h}\right)_{0,\Omega} - \left(\text{div} \sigma_{K,h}, \psi_{K,h}\right)_{0,\Omega}
\]

\[
-\frac{1}{2\rho_S} \sum_{f \in \mathcal{F}_K} (n_K \times ([\sigma]_{K,f} n_K + \rho_S [\mathbf{v}]_{K,f}), n_K \times (\varphi_{K,h} n_K + \rho_S \psi_{K,h}))_{0,f}
\]

\[
-\frac{1}{2\rho_P} \sum_{f \in \mathcal{F}_K} (n_K \cdot ([\sigma]_{K,f} n_K + \rho_P [\mathbf{v}]_{K,f}), n_K \cdot (\varphi_{K,h} n_K + \rho_P \psi_{K,h}))_{0,f}.
\]

On boundary faces \( f = \partial K \cap \partial \Omega \), we set \([\mathbf{v}_h]_{K,f} = -2\mathbf{v}_K, h \) and \([\sigma_h]_{K,f} = 0 \) for Dirichlet boundary conditions. This yields

\[
(A_h(\sigma_h, \mathbf{v}_h), (\sigma_{K,h}, \mathbf{v}_h, K,h))_{0,K} = -\sum_{f \in \mathcal{F}_K} (\mathbf{v}_K, h, \sigma_{K,h} n_K)_{0,f}
\]

\[
-\frac{1}{2\rho_S} \sum_{f \in \mathcal{F}_K} (n_K \times ([\sigma]_{K,f} n_K + \rho_S [\mathbf{v}]_{K,f}), n_K \times (\sigma_{K,h} n_K + \rho_S \mathbf{v}_K, h))_{0,f}
\]

\[
-\frac{1}{2\rho_P} \sum_{f \in \mathcal{F}_K} (n_K \cdot ([\sigma]_{K,f} n_K + \rho_P [\mathbf{v}]_{K,f}), n_K \cdot (\sigma_{K,h} n_K + \rho_P \mathbf{v}_K, h))_{0,f}.
\]

\[
\sum_{f \in \mathcal{F}_K} \left(\frac{1}{\rho_S} \|n_K \times [\sigma]_{K,f} n_K\|_{0,f}^2 + \rho_S \|n_K \times [\mathbf{v}_h]_{K,f}\|_{0,f}^2 \right. + \left. \frac{1}{\rho_P} \|n_K \cdot [\sigma]_{K,f} n_K\|_{0,f}^2 + \rho_P \|n_K \cdot [\mathbf{v}_h]_{K,f}\|_{0,f}^2 \right).
\]
For acoustic waves we obtain for \((p_h, v_h) \in H_h\) and \((\varphi_{K,h}, \psi_{K,h}) \in H_{K,h}\)

\[
\left( A_h(p_h, v_h), (\varphi_{K,h}, \psi_{K,h}) \right)_{0,K} = - \left( \text{div} \, v_{K,h}, \varphi_{K,h} \right)_{0,K} - \left( \nabla p_{K,h}, \psi_{K,h} \right)_{0,K}
- \frac{1}{2\rho c} \sum_{f \in F_K} \left( [p_h]_{K,f} + \rho c n_K \cdot [v_h]_{K,f}, \varphi_{K,h} + \rho c \psi_{K,h} \cdot n_K \right)_{0,f}.
\]

On boundary faces \(f = \partial K \cap \partial \Omega\), we set \([p_h]_{K,f} = -2p_h\) and \([v_h]_{K,f} \cdot n_K = 0\) for Dirichlet boundary conditions, and \([p_h]_{K,f} = 0\) and \([v_h]_{K,f} \cdot n_K = -2v_{K,h} \cdot n_K\) for Neumann boundary conditions. This yields

\[
\left( A_h(p_h, v_h), (p_h, v_h) \right)_{0,\Omega} = \frac{1}{2} \sum_{K \in K} \sum_{f \in F_K} \left( \frac{1}{\rho c} ||[p_h]_{K,f}||^2_{0,f} + \rho c ||n_K \cdot [v_h]_{K,f}||^2_{0,f} \right).
\]

Together with inhomogeneous boundary conditions \(p = p_{\text{stat}}\) on \(\Gamma_{\text{stat}}\) and \(n \cdot v = g_{\text{kin}}\) on \(\Gamma_{\text{kin}}\) we obtain the semi-discrete equation

\[
\left( M_h(\partial_t p_h, \partial_t v_h) + A_h(p_h, v_h), (\varphi_h, \psi_h) \right)_{0,\Omega} = \left( b, \psi_h \right)_{0,\Omega}
+ \frac{1}{\rho c} \sum_{f \in F_K \cap \Gamma_{\text{stat}}} \left( p_{\text{stat}}, \varphi_{K,h} + \rho c \psi_{K,h} \cdot n_K \right)_{0,f}
+ \sum_{f \in F_K \cap \Gamma_{\text{kin}}} \left( g_{\text{kin}}, \varphi_{K,h} + \rho c \psi_{K,h} \cdot n_K \right)_{0,f}.
\]
4 A Petrov–Galerkin space-time discretization

Let $Q = \bigcup_{R \in \mathcal{R}} \overline{R}$ be a decomposition of the space-time cylinder into space-time cells $R = I \times K$ with $K \in \mathcal{K}$ and $I \subset (0, T)$ an interval; $\mathcal{R}$ denotes the set of space-time cells. For every $R \in \mathcal{R}$ we choose local test spaces $W_{h,R} \subset L_2(R; \mathbb{R}^J)$ and we define the global test space

$$W_h = \left\{ w_h \in L_2((0, T); H) : w_{h,R} = w_h|_R \in W_{h,R} \right\}.$$ 

The functions in $W_h$ are discontinuous in space and time. Now we construct $V_h \subset H^1((0, T); H)$ with $\dim V_h = \dim W_h$. Then, functions in $V_h$ are continuous in time, i.e., $v_h(\cdot, x)$ is continuous on $[0, T]$ for a.a. $x \in \Omega$.

In the most simple case this can be achieved for a tensor product space-time discretization with a fixed mesh $\mathcal{K}$ in space and a time series

$$0 = t_0 < t_1 < \ldots < t_N = T,$$

i.e., $\mathcal{R} = \{ I_n \times K : I_n := (t_{n-1}, t_n), \ n = 1, \ldots, N, \ K \in \mathcal{K}\}$. Then, we can select a discrete space $H_h$ with $H_{h,K} = \mathbb{P}_p(K; \mathbb{R}^J)$ independently of $t$, and in every time slice we define $W_{h,R} = H_{h,K}$ constant in time on $R = I_n \times K$. For $V_h$ we use in this case piecewise linear approximations in time

$$V_h = \left\{ v_h \in H^1((0, T); H) : \right.$$

$$v_h(0, x) = 0, \ v_h(t_n, x) \in H_h \text{ for a.a. } x \in \Omega \text{ and } n = 1, \ldots, N, \text{ and }$$

$$v_h(t, x) = \frac{t_n - t}{t_n - t_{n-1}} v_h(t_{n-1}, x) + \frac{t - t_{n-1}}{t_n - t_{n-1}} v_h(t_n, x) \text{ for } t \in I_n \left\}.$$ 

In the more general case, we consider a tensor product space-time mesh with a local selection of polynomial degrees in space and time $p_R$ and $q_R$ in every cell $R$, and we set for the local test space $W_{h,R} = \mathbb{P}_{q_R-1}(I_n; \mathbb{R}^J) \otimes \mathbb{P}_{p_R}(K; \mathbb{R}^J)$. Then, the local ansatz spaces $V_{h,R} = V_h|_R$ take the form

$$V_{h,R} = \left\{ v_{h,R} \in L_2(R; \mathbb{R}^J) : \right.$$

$$v_{h,R}(t, x) = \frac{t_n - t}{t_n - t_{n-1}} v_h(t_{n-1}, x) + \frac{t - t_{n-1}}{t_n - t_{n-1}} w_{h,R}(t, x),$$

$$v_h \in V_h|_{[0,t_{n-1}]}, \ w_{h,R} \in W_{h,R}, \ (t, x) \in R = I_n \times K \left\}.$$ 

The discontinuous Galerkin operator in space is extended to the space-time operator $A_h v_h \in W_h$ by defining for $v_h \in V_h$ and $w_h \in W_h$

$$\langle A_h v_h, w_h \rangle_Q = \sum_{R \in I \times K \in \mathcal{R}} \left( \langle \text{div} F(v_{h,R}), w_{h,R} \rangle_{0,R} \right.$$

$$\left. + \sum_{f \in F_K} \langle n_K \cdot (F_{K}^{\text{num}}(v_h) - F(v_{h,R})), w_{h,R} \rangle_{0,I \times f} \right).$$

(4.1)
The discrete space-time operator $L_h \in \mathcal{L}(V_h, W_h)$ and the corresponding discrete bilinear form $b_h(\cdot, \cdot) = (L_h \cdot, \cdot)_{0,Q}$ are defined by

$$
(L_h v_h, w_h)_{0,Q} = (M_h \partial_t v_h + A_h v_h, w_h)_{0,Q}.
$$

In order to show that a solution to our Petrov–Galerkin scheme exists, we check the inf-sup stability of the discrete bilinear form $b_h(\cdot, \cdot)$ with respect to the discrete norm

$$
\|v_h\|^2_{V_h} = \|v_h\|^2_{W} + \|M_h^{-1} L_h v_h\|^2_{W}.
$$

(4.2)

By construction, $b_h(\cdot, \cdot)$ is bounded in $V_h \times W_h$, i.e.,

$$
b_h(v_h, w_h) = (L_h v_h, w_h)_{0,Q} \leq \|M_h^{-1} L_h v_h\|_W \|w_h\|_W \leq \|v_h\|_{V_h} \|w_h\|_W, \quad v_h \in V_h, \ w_h \in W_h.
$$

For the verification of the inf-sup stability, we introduce the $L_2$-projection

$$
\Pi_h : W \to W_h, \quad (\Pi_h v, w_h)_{0,Q} = (v, w_h)_{0,Q} \quad w_h \in W_h.
$$

Then, by construction, $\Pi_h A_h = A_h$ and $\Pi_h L_h = L_h$. Moreover, we define the non-negative weight function in time $d_T(t) = T - t$, and we observe

$$
\int_0^T \int_0^t \phi(s) \, ds \, dt = \int_0^T d_T(t) \phi(t) \, dt, \quad \phi \in L_1(0, T).
$$

(4.3)

**Lemma 4.1** (Lem. 3 in [8]). Assume that

$$
(M_h \partial_t v_h, d_T v_h)_{0,Q} \leq (L_h v_h, d_T \Pi_h v_h)_{0,Q}, \quad v_h \in V_h.
$$

(4.4)

Then, the bilinear form $b_h(\cdot, \cdot)$ is inf-sup stable in $V_h \times W_h$ with $\beta = 1/\sqrt{1 + 4T^2}$, i.e.,

$$
\sup_{w_h \in W_h \setminus \{0\}} \frac{b_h(v_h, w_h)}{\|w_h\|_W} \geq \beta \|v_h\|_{V_h}, \quad v_h \in V_h.
$$

Referring to [8, Thm. 4.2] we achieve that for given $f \in L_2(Q; \mathbb{R}^J)$ a unique solution $u_h \in V_h$ exists solving

$$
(L_h u_h, w_h)_{0,Q} = (f, w_h)_{0,Q}, \quad w_h \in W_h
$$

(4.5)

and satisfying the a priori bound $\|u_h\|_{V_h} \leq \sqrt{4T^2 + 1} \|M_h^{-1} \Pi_h f\|_W$.

In the following example we check assumption (4.4) in case of a tensor product discretization with homogeneous polynomial degrees in space and polynomial degree one in time ($q_R \equiv 1$). Note that for this case the Petrov–Galerkin method in time is equivalent to the implicit midpoint rule. A general proof for tensor product discretizations with arbitrary polynomial degrees is given in [8, Lem. 4.4].
Example 4.2. Let $\mathcal{R}$ be a tensor product discretization and $p_R \equiv p$ and $q_R \equiv 1$ for all $R \in \mathcal{R}$. For $v_h \in V_h$ we set $v_h^n = v_h(t_n, \cdot)$. This yields for $t \in I_n = (t_{n-1}, t_n)$

$$v_h(t, x) = \frac{t - t}{t_n - t_{n-1}} v_h^{n-1}(x) + \frac{t_n - t}{t_n - t_{n-1}} v_h^n(x),$$

$$\partial_t v_h(t, x) = \frac{1}{t_n - t_{n-1}} \left( v_h^n(x) - v_h^{n-1}(x) \right)$$

and thus $\partial_t v_h = \Pi_h \partial_t v_h \in W_h$ and $\Pi_h v_h(x, t) = \frac{1}{2} (v_h^{n-1} + v_h^n)(x)$. Due to

$$\Pi_h v_h - v_h = \frac{t_n + t_{n-1} - 2t}{2(t_n - t_{n-1})} (v_h^n - v_h^{n-1})$$

we conclude

$$\left( M_h \partial_t v_h, d_T (\Pi_h v_h - v_h) \right)_{0, Q}$$

$$= \sum_{n=1}^N \left( M_h (v_h^n - v_h^{n-1}), v_h^n - v_h^{n-1} \right)_{0, \Omega} \int_{t_{n-1}}^{t_n} d_T(t) \frac{t_n + t_{n-1} - 2t}{2(t_n - t_{n-1})^2} dt$$

$$= \sum_{n=1}^N \frac{t_n - t_{n-1}}{12} \left( M_h (v_h^n - v_h^{n-1}), v_h^n - v_h^{n-1} \right)_{0, \Omega} \geq 0$$

for all $n = 0, \ldots, N$, since $(M_h w_h, w_h)_{0, \Omega} \geq 0$ all $w_h \in W_h$.

Furthermore, $A_h = \Pi_h A_h$ yields

$$\left( A_h v_h, d_T \Pi_h v_h \right)_{0, Q}$$

$$= \left( \Pi_h A_h v_h, d_T\Pi_h v_h \right)_{0, Q}$$

$$= \sum_{n=1}^N \left( T - \frac{t_{n-1} + t_n}{2} \right) \frac{t_n - t_{n-1}}{4} \left( A_h (v_h^{n-1} + v_h^n), v_h^{n-1} + v_h^n \right)_{0, \Omega} \geq 0$$

since $T - \frac{1}{2} (t_{n-1} + t_n) \geq 0$ and $(A_h v_h, v_h)_{0, \Omega} \geq 0$ for all $v_h \in V_h$ by (3.11).

Combining both inequalities finally proves assumption (4.4).

Lemma 4.1 directly implies an a priori error estimate in the discrete graph norm (4.2). Let $h = \max_{R \in \mathcal{R}} \text{diam}(R)$ be the mesh size with $\text{diam}(R)^2 = |I|^2 + \text{diam}(K)^2$ for $R = I \times K$. For $1 \leq m \leq \min_{R} \{ p_R + 1, q_R + 1 \}$ we have

$$\inf_{v_h \in V_h \cap H^1(Q; \mathbb{R}^J)} \| v - v_h \|_{1, Q} \leq C h^{m-1} \| v \|_{m, Q}, \quad v \in H^m(Q; \mathbb{R}^J) \quad (4.6)$$

with $C > 0$ depending on the mesh quality.
Theorem 4.3 (Thm. 5 in [8]). Let \( u \in V \) be the solution of (2.3) and \( u_h \in V_h \) its approximation solving (4.5). If the solution satisfies \( u \in H^m(Q; \mathbb{R}^J) \) with \( 1 \leq m \leq \min\{p_R + 1, q_R + 1\} \), the error can be bounded by
\[
\|u - u_h\|_{V_h} \leq C h^{m-1} \|u\|_{m,Q}.
\]

Proof. Since \( M_h \) is the Galerkin projection of \( M \) in \( W \), we have
\[
b_h(u, w_h) = b(u, w_h) = (f, w_h)_{0,Q} = b_h(u_h, w_h), \quad v_h \in V_h,
\]
which yields
\[
b_h(v_h - u_h, w_h) = b_h(v_h - u, w_h) \leq \|v_h - u\|_{V_h} \|w_h\|_{W}, \quad v_h \in V_h,
\]
and thus
\[
\|u - u_h\|_{V_h} \leq \|u - v_h\|_{V_h} + \|v_h - u_h\|_{V_h}
\]
\[
\leq \|u - v_h\|_{V_h} + \beta^{-1} \sup_{w_h \in W_h \setminus \{0\}} \frac{b_h(v_h - u_h, w_h)}{\|w_h\|_{W}}
\]
\[
\leq (1 + \beta^{-1}) \|u - v_h\|_{V_h}.
\]
Now the assertion follows from \( \|v\|_{V_h} \leq C \|v\|_{1,Q} \) for \( v \in H^1(Q; \mathbb{R}^J) \) and (4.6). \qed

5 Duality based goal-oriented error estimation

In order to develop an adaptive strategy for the selection of the local polynomial degrees \( p_R, q_R \) we derive an error indicator with respect to a given linear goal functional \( E \in W' \). Following the framework in [4], we define the adjoint problem and solve the dual problem. Then, the error is estimated in terms of the local residual and the dual weight.

The adjoint operator \( L^* \) in space and time is defined on the adjoint Hilbert space
\[
V^* = \{ w \in W : \text{there exists } g \in W \text{ such that } (L v, w)_{0,Q} = (v, g)_{0,Q} \text{ for all } v \in V \}
\]
and is characterized by
\[
(v, L^* w)_{0,Q} = (L v, w)_{0,Q}, \quad v \in V, \ w \in V^*.
\]

We observe \( \{ v^* \in C^1([0, T]; D(A^*)) : v^*(T) = 0 \} \subset V^* \) and \( L^* = -L \) on \( V \cap V^* \).

For the evaluation of the error functional \( E \) we introduce the dual solution \( u^* \in V^* \) defined by
\[
(w, L^* u^*)_{0,Q} = \langle E, w \rangle, \quad w \in W.
\]
Let \( u \in V \) be the solution of (2.3), and \( u_h \in V_h \) its approximation solving (4.5). Now we derive an exact error representation for the error functional in the case that the dual solution is sufficiently smooth such that \( u^*(t, \cdot)|_f \in L^2(f; \mathbb{R}^J) \) for all faces \( f \in F_h \) and a.a. \( t \in (0, T) \). Inserting the consistency of the numerical flux (3.9) yields for all \( w_h \in W_h \cap V^* \)

\[
\langle E, u - u_h \rangle = \left( u - u_h, -M \partial_t u^* - \text{div} F(u^*) \right)_{0,Q} \\
= \left( u, -M \partial_t u^* - \text{div} F(u^*) \right)_{0,Q} - \left( u_h, -M \partial_t u^* - \text{div} F(u^*) \right)_{0,Q} \\
= \left( M \partial_t u + \text{div} F(u), u^* \right)_{0,Q} - \left( u, \text{div} F(u^*) \right)_{0,Q} \\
- \sum_{R \in \mathcal{R}} \left( \left( M \partial_t u_h + \text{div} F(u_h), u^* \right)_{0,R} - \left( u_h, \text{div} F(u^*) \right)_{0,R} \right) \\
= \left( f, u^* \right)_{0,Q} - \sum_{R = I \times K} \left( \left( M \partial_t u_h, \text{div} F(u_h), u^* \right)_{0,R} \\
- \left( u_h, \text{div} F(u^*) \right)_{0,I \times \partial K} \right) \\
= \sum_{R = I \times K} \left( \left( f - M \partial_t u_h, \text{div} F(u_h), u^* \right)_{0,R} \\
+ \left( \text{div} F(u^*), u^* \right)_{0,I \times \partial K} \right) \\
= \sum_{R = I \times K} \left( \left( f - M \partial_t u_h, \text{div} F(u_h), u^* - w_h \right)_{0,R} \\
+ \left( \text{div} F(u^*), u^* - w_h \right)_{0,I \times \partial K} \right).
\]

However, this identity cannot be evaluated numerically since it depends on the unknown function \( u^* \). In applications, the following heuristic error bound is used instead. Let \( u_h^* \in W_h \) be a numerical approximation of the dual solution given by

\[
b_h(v, u_h^*) = \langle E, v \rangle, \quad v, u_h \in V_h.
\]

Inserting some interpolation \( w_h = I_h u^* \), the interpolation error \( u^* - I_h u^* \) has to be estimated in terms of \( u_h^* \). For this purpose we use also the face jumps \([u_h^*]_{K,f}\) which are also meaningful in case of piecewise constant approximations in \( W_h \). In case of higher order approximations in \( W_h \) we use \([Q_h u_h^*]_{K,f}\), where \( Q_h \) denotes the piecewise \( L^2 \)-projection in space to \( \mathbb{P}_0(K; \mathbb{R}^J) \).

Finally, \(|\langle E, u - u_h \rangle|\) is estimated by \( \sum_{R \in \mathcal{R}} \eta_R \) with local contributions \( \eta_R \) depending on residual terms and jump terms of the discrete solution and on jump terms of the dual approximation.
For elastic waves we obtain for \((\varphi_h, \psi_h) \in W_h \cap V^*\) the error representation
\[
\langle E, (\sigma - \sigma_h, v - v_h) \rangle = \sum_{R=I \times K \in R} \left( \left( - C^{-1} \partial_t \sigma_{h,R} + \varepsilon(v_{h,R}), \sigma^* - \varphi_h \right)_{0,R} + (b - \rho \partial_t v_{h,R} + \text{div} \sigma_{h,R}, v^* - \psi_h)_{0,R} + (v_{h,R}, (\sigma^* - \varphi_h)n_K)_{0, I \times \partial K} + (\sigma_{h,R}n_K, v^* - \psi_h)_{0, I \times \partial K} \right)
\]
\[
= \sum_{R=I \times K \in R} \left( \left( - C^{-1} \partial_t \sigma_{h,R} + \varepsilon(v_{h,R}), \sigma^* - \varphi_h \right)_{0,R} + (b - \rho \partial_t v_{h,R} + \text{div} \sigma_{h,R}, v^* - \psi_h)_{0,R} + \frac{1}{2} \sum_{f \in F_K} \left( ([v_h]_{K,f}, (\sigma^* - \varphi_h)n_K)_{0, I \times f} + ([\sigma_h]_{K,f}n_K, v^* - \psi_h)_{0, I \times f} \right) \right).
\]

This motivates the local error estimate
\[
\eta_R = \| - C^{-1} \partial_t \sigma_{h,R} + \varepsilon(v_{h,R})\|_{0,R} h^{1/2}_K\| [Q_h \sigma^*_{h,K}n_K]_{0, I \times \partial K} + \| b - \rho \partial_t v_{h,R} + \text{div} \sigma_{h,R}\|_{0,R} h^{1/2}_K\| [Q_h v^*_{h,K}]_{0, I \times \partial K} + \frac{1}{2} \sum_{f \in F_K} \left( \| [v_h]_{K,f}n_K\|_{0, I \times f} \right) [Q_h v^*_{h,K}]_{0, I \times f},
\]
where the jump terms \([Q_h \sigma^*_{h,K,f}]\) and \([Q_h v^*_{h,K,f}]\) are used to estimate the best approximation error of \((\sigma^* - \varphi_h)n_K\) and \(v^* - \psi_h\).

In the same way we obtain for acoustic waves the error representation
\[
\langle E, (p - p_h, v - v_h) \rangle = \sum_{R=I \times K \in R} \left( \left( - \kappa^{-1} \partial_t p_{h,R} + \text{div} v_{h,R}, p^* - \varphi_h \right)_{0,R} + (b - \rho \partial_t v_{h,R} + \nabla p_{h,R}, v^* - \psi_h)_{0,R} + \frac{1}{2} \sum_{f \in F_K} \left( ([n_K \cdot [v_h]_{K,f}, p^* - \varphi_h)_{0, I \times f} + ([p_h]_{K,f}, n_K \cdot (v^* - \psi_h))_{0, I \times f} \right) \right).
\]
and the local error estimate
\[
\eta_R = \| - \kappa^{-1} \partial_t p_{h,R} + \text{div} \mathbf{v}_{h,R} \|_{0,R} h_R^{1/2} \| [Q_h p_h^*]_K \|_{0,I \times \partial K} \\
+ \| \mathbf{b} - \rho \partial_t \mathbf{v}_{h,R} + \nabla p_{h,R} \|_{0,R} h_R^{1/2} \| \mathbf{n}_K \cdot [Q_h \mathbf{v}_h^*]_K \|_{0,I \times \partial K} \\
+ \frac{1}{2} \sum_{f \in \mathcal{F}_K} \left( \| [\mathbf{v}_h]_{K,f} \|_{0,I \times f} \| [Q_h \mathbf{p}_h^*]_{K,f} \|_{0,I \times f} \\
+ \| [p_h]_{K,f} \mathbf{n}_K \|_{0,I \times f} \| \mathbf{n}_K \cdot [Q_h \mathbf{v}_h^*]_{K,f} \|_{0,I \times f} \right).
\]

In our examples we use the adaptive strategy for \( p \)-refinement described in Algorithm 1. It depends on a parameter \( \vartheta < 1 \) for the adaptive selection criterion.

**Algorithm 1** Adaptive algorithm.

1: choose low order polynomial degrees on the initial mesh
2: while \( \max_R (p_R) < p_{\text{max}} \) and \( \max_R (q_R) < q_{\text{max}} \) do
3: compute \( u_h \)
4: compute \( u_h^* \) and the projection \( Q_h u_h^* \)
5: compute \( \eta_R \) on every cell \( R \)
6: if the error is small enough STOP
7: mark space-time cell \( R \) if \( \eta_R > \vartheta \max_{R'} \eta_{R'} \)
8: increase polynomial degrees on marked cells by one
9: redistribute cells on processes for better load balancing
10: end while

### 6 Space-time multilevel preconditioner

In this section we address the numerical aspects and in particular solution methods for the discrete hyperbolic space-time problem. First we describe the realization of our discretization using nodal basis functions in space and time, and then a multilevel preconditioner is introduced.

**Nodal Discretization** Now we consider the structure of the linear system for the special case of a tensor product space-time mesh \( \mathcal{R} = \bigcup_{n=1}^N \mathcal{R}^n \) with time slices \( \mathcal{R}^n = \{ I_n \times K : K \in \mathcal{K} \} \) and variable polynomial degrees \( p_R, q_R \) in every space-time cell \( R \), cf. Sect. 4. Let \( \{ \psi_{R,j}^n \}_{j=1,\ldots,\dim W_{h,R}} \) be a basis of \( W_{h,R} \) and define \( W_h^n = \text{span} \left\{ \bigcup_{R \in \mathcal{R}^n} \bigcup_{j=1}^{\dim W_{h,R}} \psi_{R,j}^n \right\} \). Then, the solution \( u_h \in V_h \) is represented by finite element functions \( u_h^n \in W_h^n, n = 1, \ldots, N \). Together with \( u_h^0 = 0 \) we obtain

\[
u_h(t, x) = \frac{t_n - t}{t_n - t_{n-1}} u_{h-1}^{n-1}(t_{n-1}, x) + \frac{t - t_{n-1}}{t_n - t_{n-1}} u_h^n(t, x), \quad (t, x) \in I_n \times K.
\]
The corresponding coefficient vector of the solution is denoted by \( u = (u^1, \ldots, u^N)^\top \), where \( u^n \in \mathbb{R}^{\dim W^n_h} \) is the coefficient vector of \( u^n_h = \sum_{R \in \mathcal{R}_n} \sum_{j=1}^{\dim W_{h,R}} u^n_{R,j} \psi^n_{R,j} \). With respect to this basis, the discrete space-time system (4.5) has the matrix representation \( L u = f \) with the block matrix
\[
L = \begin{pmatrix}
D^1 & D^2 & \cdots & \cdots & D^N \\
C^1 & \cdots & \cdots & \cdots & \cdots \\
\cdots & \cdots & \cdots & \cdots & \cdots \\
C^{N-1} & D^N
\end{pmatrix}
\]
and matrix entries
\[
D^n_{R',R,j} = \int_{t_{n-1}}^{t_n} \int_{\Omega} L_h \left( \frac{t-t_{n-1}}{t_n-t_{n-1}} \psi^n_{R,j}(t,x) \right) \psi^n_{R',k}(t,x) \, dx \, dt, \quad R, R' \in \mathcal{R}_n
\]
\[
C^n_{R',R,j} = \int_{t_{n-1}}^{t_n} \int_{\Omega} L_h \left( \frac{t_{n-1}-t}{t_{n-1}-t_n} \psi^{n-1}_{R,j}(t_{n-1},x) \right) \psi^n_{R',k}(t,x) \, dx \, dt, \quad R \in \mathcal{R}_{n-1}, \ R' \in \mathcal{R}_n,
\]
and the right-hand side \( f = (f^1, \ldots, f^N) \) with \( f^n_{j,R} = (f, \psi^n_{R,j})_{0,R} \). Sequentially, this system can be solved by a block-Gauss–Seidel method (corresponding to implicit time integration)
\[
D^1 u^1 = f^1, \quad D^2 u^2 = f^2 - C^1 u^1, \quad \ldots, \quad D^N u^N = f^N - C^{N-1} u^{N-1},
\]
provided that \( D^n \) can be inverted efficiently.

**Multilevel methods** For space-time multilevel preconditioners we consider hierarchies in space and time. Therefore, let \( \mathcal{R}_{0,0} \) be the coarse space-time mesh, and let \( \mathcal{R}_{l,k} \) be the discretization obtained by \( l = 1, \ldots, l_{\text{max}} \) uniform refinements in space and \( k = 1, \ldots, k_{\text{max}} \) refinements in time. Let \( V_{l,k} \) be the approximation spaces on \( \mathcal{R}_{l,k} \) with fixed polynomial degrees \( p_R \equiv p \) and \( q_R \equiv q \). Let \( L_{l,k} \) be the corresponding matrix representation of the discrete operator \( L_h \) in \( V_{l,k} \).

The multilevel preconditioner combines smoothing operations on different levels and requires transfer matrices between the levels. Since the spaces are nested, we can define prolongation matrices \( P^{l,k}_{l-1,k} \) and \( P^{l,k}_{l,k-1} \) representing the natural injections \( V_{l-1,k} \subset V_{l,k} \) in space and \( V_{l,k-1} \subset V_{l,k} \) in time. Correspondingly, the restriction matrices \( R^{l,k}_{l-1,k} \) and \( R^{l,k}_{l,k-1} \) represent the \( L_2 \)-projections in space and in time of the test spaces \( W_{l,k} \supset W_{l-1,k} \) and \( W_{l,k} \supset W_{l,k-1} \).

For the smoothing operations on level \((l,k)\) we consider the block-Jacobi preconditioner or the block-Gauss–Seidel preconditioner (where all components corresponding
to a space-time cell \( R \) build a block)
\[
B^1_{l,k} = \theta_{l,k} \text{block}_\text{diag}(L_{l,k})^{-1},
\]
\[
B^{\text{GS}}_{l,k} = \theta_{l,k} (\text{block}_\text{lower}(L_{l,k}) + \text{block}_\text{diag}(L_{l,k}))^{-1}
\]

with damping parameter \( \theta_{l,k} \in (0, 1] \). The corresponding iteration matrices are given by
\[
S^1_{l,k} = \text{Id}_{l,k} - B^1_{l,k} L_{l,k}
\]
and
\[
S^{\text{GS}}_{l,k} = \text{Id}_{l,k} - B^{\text{GS}}_{l,k} L_{l,k},
\]
and the number of pre- and post-smoothing steps are denoted by \( \nu_{l,k}^{\text{pre}} \) and \( \nu_{l,k}^{\text{post}} \).

Now, the multilevel preconditioner \( B_{l,k}^{\text{ML}} \) is defined recursively. On the coarse level, we use a parallel direct linear solver \( B_{0,0}^{\text{ML}} = (L_{0,0})^{-1} \), see [26, 27]. Then, we have two options: restricting in time defines \( B_{l,k}^{\text{ML}} \) by
\[
\text{Id}_{l,k} - B_{l,k}^{\text{ML}} L_{l,k}
\]
with Jacobi smoothing, and restricting in space yields
\[
\text{Id}_{l,k} - B_{l,k}^{\text{ML}} L_{l,k}
\]
with Gauss–Seidel smoothing. Our tests in [8] indicate that it is advantageous to start with refinement in time and then refinement in space, i.e., we use the sequence of meshes \( R_{0,0}, R_{0,1}, \ldots, R_{0,k_{\text{max}}}, R_{1,k_{\text{max}}}, \ldots, R_{l_{\text{max}},k_{\text{max}}} \) (see Algorithm 2 for the recursive realization of the multilevel preconditioner).

**Algorithm 2** Multilevel preconditioner \( \varrho_{l,k} = B_{l,k}^{\text{ML}} \tau_{l,k} \) with Gauss–Seidel smoother \( B_{l,k}^{\text{SM}} = B_{l,k}^{\text{GS}} \) in space for \( l > 0 \) or Jacobi smoother \( B_{0,k}^{\text{SM}} = B_{0,k}^{\text{J}} \) in time

1: \( \varrho_{l,k} = 0 \)
2: for \( \nu = 1, \ldots, \nu_{l,k}^{\text{pre}} \) do
3: \( \varrho_{l,k} := B_{l,k}^{\text{SM}} \tau_{l,k} \)
4: \( \varrho_{l,k} := \varrho_{l,k} + \nu_{l,k}^{\text{pre}} \) and \( \tau_{l,k} := \tau_{l,k} - \Delta_{l,k} \nu_{l,k}^{\text{pre}} \)
5: end for
6: \( \tau_{l-1,k} = B_{l-1,k}^{\text{J}} \tau_{l,k} \) for \( l > 0 \) or \( \tau_{0,k-1} = B_{0,k-1}^{\text{J}} \tau_{0,k} \)
7: \( \varrho_{l-1,k} := B_{l-1,k}^{\text{ML}} \tau_{l-1,k} \) for \( l > 0 \) or \( \varrho_{0,k-1} := B_{0,k-1}^{\text{ML}} \varrho_{0,k-1} \)
8: \( \nu_{l-k}^{\text{pre}} = B_{l-k}^{\text{J}} \nu_{l-k}^{\text{pre}} \) for \( l > 0 \) or \( \nu_{0,k}^{\text{pre}} = B_{0,k}^{\text{J}} \nu_{0,k}^{\text{pre}} \)
9: \( \varrho_{l,k} := \varrho_{l,k} + \nu_{l,k}^{\text{pre}} \) and \( \tau_{l,k} := \tau_{l,k} - \Delta_{l,k} \nu_{l,k}^{\text{pre}} \)
10: for \( \nu = 1, \ldots, \nu_{l,k}^{\text{post}} \) do
11: \( \nu_{l,k}^{\text{pre}} = B_{l,k}^{\text{SM}} \nu_{l,k}^{\text{pre}} \)
12: \( \varrho_{l,k} := \varrho_{l,k} + \nu_{l,k}^{\text{pre}} \) and \( \tau_{l,k} := \tau_{l,k} - \Delta_{l,k} \nu_{l,k}^{\text{pre}} \)
13: end for
7 Numerical experiments

We illustrate the numerical performance of the space-time method with two examples. The first test is a simple plane wave solution for the acoustic problem where the solution is known so that we can test the convergence properties for uniform \( h \)- and \( p \)-refinement. The second example is application-oriented and shows the behavior of the \( p \)-adaptive algorithm for a configuration motivated from tunnel exploration.

In all cases the linear systems are solved approximately with a GMRES iteration and the space-time multigrid preconditioner. As general multigrid parameters we use for coarsening in time a damped block-Jacobi preconditioner (\( \theta = 0.5 \)) with 2 pre- and post-smoothing steps, and for coarsening in space a block-Gauss–Seidel preconditioner with 5 pre- and post-smoothing steps. A V-cycle with coarsening the mesh first in space and then in time is applied. All computations use multigrid over three levels in space and in time.

The adaptive refinement starts with a finite volume discretization in space (\( p = 0 \)), and linear ansatz and constant test functions in time on each space-time cell (\( q = 1 \)). The algorithm increases in the first step adaptively the polynomial degrees in space and later the polynomial degrees in space and time simultaneously. The approximation spaces \( V_{l,k} \) are chosen such that the polynomial degrees on each cell is the maximum over all corresponding cells of the fine mesh. For the underlying 2D mesh in space we use quadrilaterals.

7.1 A benchmark experiment

The first example is specially designed for a convergence test. We use the time interval \((0, T) = (0, 4)\) and the spatial domain \( \Omega = (-2, 4) \times (0, 2) \subset \mathbb{R}^2 \) with piecewise constant parameters

\[
\rho(x_1, x_2) = \begin{cases} 
1 & x_1 < 0, \\
2 & 0 < x_1 < 1, \\
1/2 & 1 < x_1,
\end{cases} \quad \text{and} \quad \kappa(x) = 1/\rho(x).
\]

Starting with

\[
u_0(x) = A(x_1) \begin{pmatrix} 1 \\ 1 \\ 0 \end{pmatrix} \quad \text{for } A(x_1) = \begin{cases} 
\cos((x_1 - 1)\pi/2)^6 & -2 < x_1 < 0, \\
0 & \text{else}
\end{cases}
\]

results in the plane wave solution with

\[
u(t, x_1, x_2) = \begin{cases} 
u_0(x_1 - t, x_2) & x_1 \leq 0, \\
u_0(2x_1 - t, x_2) & 0 < x_1 \leq 1, \\
u_0(2 + 0.5(x_1 - 1) - t, x_2) & 1 \leq x_1.
\end{cases}
\]
Figure 1. Benchmark experiment: The initial wave will travel from the left to the right. Sketch of the impulse (left) and pressure component of the space-time solution (right).

The computed experimental orders of convergence are shown in Table 3. We observe the expected order of convergence as predicted in Theorem 4.3 for sufficiently smooth solutions.
7.2 A tunnel experiment

The second example illustrates seismic tunnel exploration: An artificially generated surface wave in the tunnel propagates into the solid and the reflected waves are measured in a certain region. Here, we compare the results of acoustic and elastic waves.

We choose a rectangular domain $\Omega \subset (-2, 2) \times (-1.5, 2.5) \subset \mathbb{R}^2$ and we use density $\rho = 1$, Lamé parameters $\lambda = 0.5$ and $\mu = 0.25$ for the elastic wave equation. This results in compression waves with velocity $c_p = (2\mu + \lambda)/\rho = 1$ and shear waves with velocity $c_s = \sqrt{\mu/\rho} = 0.5$. In the acoustic case we use the parameters $\rho = \kappa = 1$, so that the velocity of sound $c = \sqrt{\kappa/\rho} = 1$ is equal to the wave propagation speed of the elastic compression waves.

At $t = 0$ we start with a smooth pulse located at $x_{\text{mid}} = (0.5, 1) \in \partial\Omega$ defining the initial velocity

$$v_0 = \begin{pmatrix} x_1 - 0.5 \\ x_2 - 1.0 \end{pmatrix} \phi \quad \text{with} \quad \phi(x) = \begin{cases} \cos^6(2\pi|x_{\text{mid}} - x|^2) & |x_{\text{mid}} - x|^2 < 0.25, \\ 0 & \text{else}. \end{cases}$$

In the acoustic case we set $p_0 \equiv 0$ and in the elastic case $\sigma_0 \equiv 0$.

![Figure 2](image)

Figure 2. Tunnel experiment: Sketch of the computational domain $\Omega$ with marked region of interest RoI.

In applications the velocity is measured at certain points within a region of interest RoI; here we use $\text{RoI} = (0.5, 1) \times (0.5, 1)$, cf. Figure 2. Since we are interested in the velocity at the final time $T = 3$, we consider the linear goal functional

$$E(v) = \frac{1}{|\text{RoI}|} \int_{\text{RoI} \times \{T\}} v_1 \, dx.$$ 

The smooth pulse starts at $x_{\text{mid}}$ and expands through the domain. After being reflected at the right boundary, the wave reaches back to the region of interest. The visualization is obtained by slicing through the space-time mesh, see Figure 3.
Figure 3. Acoustic wave: Slices through the space-time mesh of the pressure component.

(a) $t = 0.0$  
(b) $t = 0.6$  
(c) $t = 1.2$  
(d) $t = 1.8$  
(e) $t = 2.4$  
(f) $t = 3.0$

Table 4. Acoustic wave: Uniform vs. adaptive refinement on 44,544 = 928 × 48 space-time cells distributed on 64 processor cores. The error $\Delta E_{\text{ex}}(u_h) = |E(u_h) - E_{\text{ex}}|$ of the goal functional is approximately estimated with respect to a linear extrapolation of the uniform results $E_{\text{ex}} = 4.9052e-3$.

The results for the uniform and adaptive refinement in the acoustic case are given in Table 4. We observe that the adaptive algorithm saves over 70% of the degrees of freedom while achieving the same accuracy compared with uniform refinement.
Table 5. Elastic wave: Uniform vs. adaptive refinement on $44,544 = 928 \times 48$ space-
time cells distributed to 64 processor cores (for uniform computations $p = q \leq 3$ due to
memory restrictions). The error of the goal functional is approximately estimated with
respect to $E_{ex} = 1.9057e-3$.

Comparing the acoustic wave in Figure 3 with the results in Figure 5 for the elastic
wave we can see the additional shear wave which propagates with half of the velocity
behind the compression wave. The acoustic wave equation in 2D has three components
and the elastic wave equation has five components. This results in more DoF and thus
in larger matrices. To save random access memory in this case we use as approxima-
tion spaces $V_{l,k}$ on the coarser meshes a lowest order finite volume discretization. The
results for uniform and adaptive refinement in the elastic case are shown in Table 5
and illustrated in Figure 5, which demonstrates the excellent efficiency of the adaptive
scheme.

Figure 4. Tunnel Experiment: Strong scaling for $\sim 34$ Mio. DoFs (acoustic wave).
The parallel scaling behavior of the parallel multilevel preconditioner is tested for different numbers of processes. On mesh level 4 we have 2,850,816 space-time cells, a linear discretization in space and time results in 34,209,792 DoFs for the acoustic case. The computing time for solving this huge linear system system with the parallel multigrid method scales nearly optimal\(^1\), cf. Figure 4.
